An Intelligent Approach to Theater Ballistic Missile Attack Operations

Lt Col Rocky Farry Maj Bill Treu

I. Theater Ballistic Missile Defense - Why Such A Fuss?

Ever since the Gulf war, a great deal of effort has been focused on the threat of theater ballistic missiles (TBM) and programs to counter this increasing threat. Yet, many military commanders may have the opinion that in a war, with the expectation that TBMs can do relatively little real damage with high explosive (HE) or even chemical warheads, their efforts are better directed elsewhere. What many may not fully appreciate, however, is that the mere threat of TBMs by third world nations will likely cause the national command authority to direct the theater commander to take significant measures to combat them regardless of whatever minimal real damage is postulated by the commander. Additionally, the likelihood that TBMs will actually be equipped with chemical warheads is increasing, and nuclear/ biological warheads are on the horizon. In the absence of a preconflict plan that establishes a credible approach, available assets will be wasted in the resulting last-minute attempt to deal with the problem.

In a relatively short span of time, the theater ballistic missile (TBM) threat has grown from a well-known but largely tactical threat to a major politico-military problem. Theater missiles have been in existence for years, but during the cold war era the only non-NATO country with a viable capability was the Soviet Union. Having intercontinental ballistic missiles, the Soviets used their Scud missiles primarily as battlefield support weapons. Equipped with chemical or HE warheads, the missiles were a recognized threat, but a relatively minor one in the context of the vast European East-West conflict. Today, however, TBM's have achieved a new dimension in the hands of hostile or unstable third world nations, many of which are developing nuclear, biological and chemical (NBC) capabilities for which the Scud and other such missiles are an acceptable delivery vehicle.

For many third-world nations, TBMs are a substitute for the intercontinental capabilities of the two cold war superpowers, resulting in a powerful political and economic presence hitherto unattainable. In peacetime, possession of TBMs yields threat countries a level of influence in regional and global affairs that is far out of proportion to the purely destructive force of a TBM. During a conflict, the likelihood of TBM operations can encourage or discourage nations from participating in the hostilities. (1) For example, the use of the Scud missile by Iraq against Israel very nearly succeeded in drawing Israel into the conflict. Additionally, possession of a NBC equipped TBM force allows an otherwise militarily defeated country to threaten the use of NBC in order to obtain, for example, an acceptable cease-fire agreement, thus avoiding the penalties of a lost cause. This capability may encourage military adventures since the aggressor is secure in the knowledge that, even in defeat, a final adverse reckoning probably will not occur.

Finally, there are good economic reasons for a nation to pursue development of a TBM force. The requirement for a large number of conventional weapons may be replaced with a small and relatively inexpensive TBM force acknowledging, of course, the targeting limitations of specific types of missiles. For example, many third world nations expend inordinate amounts of money and effort in developing air forces. These air forces are in many cases of questionable value, especially when considering maintenance or operational readiness of personnel. Against a superpower such as the US, they are almost assured of negation in short order. A TBM force not tied to a large operating base is more survivable and cost effective than a conventional air force for most strategic requirements.

II. So What Are We Doing About It?

Given the above factors and the likelihood that the US will again face an opponent armed with a significant TBM force, a great deal of time, money and effort has gone into solving the Theater Missile Defense (TMD) problem. Historically there are three "pillars" comprising theater missile defense: active defense, passive defense, and attack operations. Active defense addresses the efforts to engage and shoot down a missile once it has been launched. Passive defense consists largely of warning personnel in threatened areas prior to missile impact. Attack operations are those conducted to find and destroy TBM elements on the ground. In addition to these three pillars the underlying Battle Management, Command, Control, Communications, Computers, and Intelligence (BMC4I) infrastructure enables the other pillars to be expeditiously and effectively conducted.

Active defense thus far has received the lion's share of public attention, and, to some extent, justifiably so. During the Gulf War, active defense was the only activity that produced concrete results in the form of Scud missile kills. Consequently, efforts to continue upgrading our active defense capabilities including Boost Phase Intercept (BPI), should definitely be supported. (2) However, because of the past emphasis placed on active defense, other pillars such as attack operations have been overshadowed. Most importantly, however, is the fact that even though attack operations tests have been and continue to be conducted, with a few notable exceptions most of these test programs are narrowly focused against the transporter-erector-launcher (TEL) detection, identification, and attack. These test efforts do not address the full spectrum of attack operations, the purpose of which is to destroy or degrade the opponents entire theater missile launch, resupply, and reconstitution infrastructure and disrupt the tempo of TBM operations to the extent that they become ineffective. (3)

III. Why Do We Need Attack Operations?

Given that we are going to have to defend against TBMs, some may argue why we need attack operations at all. If we can shoot down any incoming missiles with active defense, why should we take available attack assets away from other tasks to do this? Doesn't active and passive defense take care of the problem?

There are many shortfalls to the current approach to TBM operations. Overreliance on the active defense pillar to the partial exclusion of the other pillars has some distinct drawbacks. Active defense is essentially a <u>reactive</u> and not a proactive approach. By waiting for a missile to launch,

we leave the initiative to the enemy as to the time, place, and weight of attack. With the ranges of TBM's continually increasing, we may not have systems such as Patriot or THAAD in position to protect potential targets. Even if present, we may not be able to intercept incoming missiles in time to prevent detonation over friendly territory. Additionally, maneuvering warheads and other technically feasible countermeasures may degrade current capabilities. Total reliance on active defense also means that we are unable to attrit the threat before it becomes an immediate defense problem. As a result the active defense assets may be oversaturated by enemy TBM surge operations. Another consideration is that over time even third world enemies may develop jamming capabilities, or other methods that may degrade our ability to detect and target missiles in flight. A total reliance on active defense in this instance means no effective defense at all.

IV. So Lets Focus On The Launches And Go Get The TEL's

If we accept the notion that, based on the above arguments we should conduct attack operations, some people may feel the idea is to get right at the mobile launchers, the TELs, after launch. After all, they reason, the TEL is the most mission critical element on the ground and it carries the threat missile, so that should be the focus of all our attack operations. We know right away when the missile launches, so all we have to do is improve the timelines to get an attack asset near that spot as soon as possible. Therefore we should primarily focus on programs that ensure attack assets have the necessary sensors on board to detect and identify once on the scene, right?

Partly right. Obviously, for active defense measures, the launch is event which cues active defense assets to detect and subsequently destroy the missile in flight. However, TBM elements are most visible at the time of the launch and any enemy is quite aware of this. Because current blue force attacks are overly dependent on launches, time-critical attacks are generated at a time when opposing TBM forces suspect or know they are being looked at. Within a short amount of time after launch, an intelligent enemy will be trying to conceal himself from attack. By the time blue forces arrive in the vicinity of a launch they are faced with a paradox. While knowing enemy TBM forces are in the area and thus narrowing the scope of the search, attack assets are even less likely to find and destroy individual vehicles than normal because of the camouflage, concealment, and deception (CC&D) measures conducted by a self-conscious opponent. Although improvements are being made to current attack platforms, the evidence provided by Desert Storm should give pause to those who look to this as the solution. (4) There is no evidence that our capabilities are significantly greater than those present in the Gulf War. It should also be remembered that with TBM operations, except in very unusual circumstances, the enemy has the initiative regarding when, where, and at what force level attacks will take place. Therefore, secure hide sites an intelligently selected distance from the launch point can be expected to be prepared in advance. Launch vehicles will move quickly after missile launch to reduce the possibility of detection and destruction.

V. What Can We Do Besides TEL-Killing?

If we don't have a realistic ability to find and kill the TEL's after launch with attack assets, many may argue that we are unable to have an effect on TBM operations. This section provides some available alternatives:

A. Pre-planned/Deferred Gratification Operations - As the title suggests, these are targets that would be built into an Air Tasking Order (ATO) for the next day's operations. These operations can be geared toward reconnaissance or strikes but to a far greater degree than time-critical attacks, are very dependent on focused intelligence analysis (i.e. Actionable Intelligence - see detailed section below). A well thought-out operational plan of attack will, rather than being reactionary, force the opponent to modify his launch plans as a result of air operations. Many of these pre-planned operations can be considered "deferred gratification" operations because the results of these efforts may not be immediately observable or even detectable. For example, it may be difficult to tell if pre-planned strikes have truly disrupted a planned launch cycle or whether a hiatus or reduction in launch activity was already planned by an opponent. Additionally, as in the case of road mining, destruction of TBM elements may not occur until hours or days after the strike, depending on the circumstances and tempo of TBM operations. Depending on the scale of conflict and time involved, much of the initial work required may have to be prepared in advance of the conflict due to the sensor and analytical workload that increases in the middle of a war. (In effect, reducing the baseline research capability necessary for proper preplanning.) Pre-planned operations, properly conducted, give the commander a wide array of options as to how to conduct the anti-TBM campaign. Unlike time-critical attacks whose only goal is to destroy TBM launch forces in the field, the ability to prosecute pre-planned attacks gives the commander the option to pursue any one of a number of goals, some of which will subsequently aid time-critical attacks. These goals include but are not necessarily limited to: disrupting the TBM tempo of operations, destruction of forward bases or individual launch elements, channelization of TBM assets into areas we desire for subsequent attack operations, and forcing the opponent to use a less than optimum plan due to the weight of attack.

1) Pre-planned Reconnaissance - To make the most effective use of available reconnaissance sensors, (many of which have limited fields of view at high resolution) the most likely areas of TBM operations should, to the extent possible be identified in advance. Thus when a potential crisis evolves into an actual shooting war, the probability of detecting and identifying TBM launch and support elements improves with a focused collection effort.

2) Pre-planned Surveillance missions - As opposed to reconnaissance tasking, pre-planned surveillance includes the identification of suitable areas for, tasking, and insertion of unattended ground sensors (UGS) or special operations forces whose primary purpose is to detect, identify, and report TBM assets for subsequent attack. Depending on the type of sensor used, these operations will require differing lead times. In the case of air-droppable UGS, missions would be incorporated into the ATO as part of the interdiction effort while sensors requiring hand-emplacement would require more extensive planning and time. Insofar as attack operations are concerned, contact reports generated by these surveillance activities can be used to generate immediate time-critical attacks on vehicles or activities detected. If additional confirmation is desired, these detections can be used to contact reporting is that opposing TBM forces are unaware they are being watched until attack forces arrive in the area, as opposed to the immediate post-launch period when they are quite aware. Used in another way, immediate attacks may be deferred in favor of further surveillance to determine TBM patterns of movement. A series of detections may allow analysts to make judgements regarding the relationship of

launch areas to support bases so that these facilities can be pinpointed and subjected to attacks, the results of which may have far more of a lasting impact than individual vehicle destruction.

3) Interdiction and fixed-site destruction - These attack operations, built into the ATO, include road mining of key lines of communication for TBM operations, destruction of non-by-passable key bridges, and attacks on in-field TBM support sites following identification from reconnaissance assets. In the case of road interdiction these operations may be implemented prior to a contact report in a pre-planned way based on the knowledge that TBM elements must or probably will use certain lines of communication to get from launch points to in-field support areas and bases. Attacks on in-field support sites will likely cause the most long-term disruption in TBM operations. These forward support bases house the resupply missiles and support vehicles necessary for a sustained TBM campaign. However, these types of facilities can only be identified when a merger of focused reconnaissance and analysis takes place, since likely areas for support bases must be pre-identified for reconnaissance tasking. Even more importantly however, in-field support sites used in wartime may in fact be facilities devoted to other uses in peacetime, the only requirements being the ability to store resupply missiles, access to lines of communication, and a certain amount of covered storage for vehicles. Even where available imagery may contain an in-field support base, the essential identification as to the true purpose of this otherwise innocuous facility is dependent upon experienced analysts that are familiar with TBM operations and equipment, knowledge of the target country infrastructure, and ability to differentiate normal from abnormal patterns of movement or activity. Only then can a positive identification be made and the facility placed on a target list or selected for immediate strike.

B. Time-Critical Targeting (TCT) - As stated above, much effort has already been devoted to attacking TBM elements in the field immediately following launch, with the launch itself providing the contact report. Depending on the amount of baseline research and analysis already conducted, the operational commander may pursue a variety of courses. High resolution sensor platforms may be dispached to the area to acquire and positively identify the TEL. If an attack is to be conducted immediately, aircraft may be dispached with the goal of finding and destroying the TEL itself, sowing mines in the immediate area along the lines of communication the TEL is currently traveling on or may have to use later for resupply purposes, or destroying key bridges with the same intent. Due to the immediacy of these attacks, the latter options require that key LOC points and bridges be identified and coordinates known in advance. Although post-launch TBM attacks may be successful, overreliance on this approach also means that, even when successful, a TEL that is destroyed is almost certainly bereft of a missile, having just launched it.

VI. What Should Be The Role Of Intelligence?

This sounds good, some may argue, but just how is all of this supposed to happen and why can't it be done as the crisis develops as part of the initial response? With the recent downsizing, why should we devote scarce resources and personnel in peacetime to do it?

All of the above operations, especially pre-planned strikes, are heavily dependent on intelligence reconnaissance and analysis for success. For any given country much of this work must be accomplished in advance for the best possibility of success. As was seen during the Gulf War, when engaged in an actual shooting war, competition for available reconnaissance assets

increases dramatically and thereby reduces the availability of a large amount of imagery for the TMD task. (5) This is due to the need for imagery to support pre-strike planning, post-strike battle damage assessment (BDA), current ground situation awareness, and other necessary timecritical mission essential tasks. During peacetime, many of these factors do not exist and therefore do not interfere with available reconnaissance opportunities. Another consideration is the fact that in the middle of a war available intelligence analysts are likely engaged full time fighting daily "fires", and in all probability do not have the time to conduct an in-depth and necessarily time consuming background study of the type required. (6) Add to this the fact that since the Gulf War our pool of qualified analysts has declined and the likelihood that most of the available military analysts in theater will not have solid TBM backgrounds or knowledge of the steps necessary to achieve the goal will only exacerbate the problem. Peacetime intelligence staffing shortages such as those which negatively affected CENTCOM prior to the Gulf War will continue to be the rule rather than the exception. (7)

The essential goal for intelligence in countering TBM operations is to take an initially large geographic area in which it appears TBM elements may operate and reduce this area to individual locations where these elements are actually or probably situated. This represents actionable intelligence in the sense that further reconnaissance or attack operations can be conducted as an immediate result of the intelligence process. The process starts with a mass of intelligence and country data available in peacetime and progresses through a series of steps that flows logically through the peacetime, crisis, and hostilities phases. This process is Intelligence Preparation of the Battlespace (IPB).

VII. What Is IPB For Theater Ballistic Missiles And Why Do We Need It?

In peacetime, or at the very latest, during the crisis phase it is essential that an Intelligence Preparation of the Battlespace (IPB) focused on TBM be conducted for each potential threat region. Only through this step-by-step process can likely TBM areas of operation and potential targets be identified in advance. The IPB is to be further prosecuted in the crisis and hostilities phases. According to army field manual FM 34-130, IPB is a continuous process of analyzing the enemy, weather, and terrain in a specific geographic region. (8) IPB is nothing new for army personnel, however air force and navy personnel may be unfamiliar with this process because the purpose for most IPB development is preparation for large-scale ground force operations. In a typical IPB effort various templates, including situational, doctrinal, event, and others are produced to support the ground campaign. However since TBM operations are unique compared to other ground maneuver forces and the targeted elements are more individual in nature, a TBM-specific process must take place although existing IPB information is used. The goals of this peacetime TBM IPB effort are to determine first the likely areas of TBM operations and then, within these areas, identify potential wartime TBM field support sites, hide or launch sites, mineable sections and bridges along key lines of communications for TBM operations, and good locations for the placement of ground sensors. The product of this IPB process is a TBM template, the areas and targets of which are depicted in hardcopy or preferably in an intelligence data base for graphic display and quick information retrieval.

VIII. How Must This Process Be Accomplished To Have Worthwhile IPB Products?

The IPB process begins with an evaluation of the threat, including the capabilities and limitations of available TBM's, operational doctrine of the host country, and equipment related factors. Incorporated into this evaluation is an evaluation of threat country intentions, to include political, military, and economic objectives from which it may be possible to determine the likely friendly targets of attack. With these evaluations in hand, an initial template can be developed that shows the area within which the opponent can conduct operations and still be within range of the intended targets. Once this has been accomplished, analysis of terrain and weather within this area including ground slope, elevation, vegetation, seasonal variances, and other pieces of data can, in conjunction with the threat data, help focus the likely areas of TBM operations. Within each of these likely TBM operating areas, imagery can be obtained and searched to accomplish the goals stated above. However, this final step requires that imagery for all portions of anticipated TBM operations be available. In reality, imagery of the entire threat country should be available since 1) Depending on the threat country, terrain and weather may not limit TBM operating areas to a considerable degree 2) The identified TBM operating areas may prove to be wrong in wartime, necessitating a rapid refocus on the areas where launches are occurring, thus requiring imagery and 3) Having imagery of the entire country beforehand means a graphical template in either hardcopy or softcopy form can be prepared in advance and overlaid on a map base to instantly associate any piece of terrain with an individual image or images. The purpose for this imagery template would be to provide baseline reference images for area and fixed point study, not the current battle situation, and therefore current collection would not be required for this purpose. Additionally, as hostilities progress, this quick retrieval capability would allow analysts to compare newly acquired wartime imagery with peacetime to note differences, look at suspected areas of TBM operations before tasking new collection, and quickly respond to imagery requests that do not require new collection, such as information on an industrial facility or other relatively unchanging ground target set. As indicated in preceding paragraphs, this requirement for imagery is one reason why it is imperative that the IPB be done prior to hostilities, since it is unlikely that imagery, if not already available, can be acquired in the amount required, catalogued, added to an imagery template, and searched in its totality by analysts during the actual shooting war.

Provided that the above efforts have been conducted and the resulting template is in hand, when a crisis arises in the region available reconnaissance assets can be focused in on the likely TBM areas and potential targets, rather than having to attempt to search the entire country, an impossible task in any case. In those cases where actual TBM elements are confirmed present, these locations and associated lines of communication targets can be fed into a target list or further information gathered.

During the actual hostilities phase, all the activities of the crisis phase take place with the addition that launch events are being conducted and intelligence analysts have focused areas within which to modify the TBM template. It should be remembered that IPB is a <u>process</u> and the same processes used in the development of the template are used in refocusing efforts for the newly revealed TBM operating areas if these prove to be different from those anticipated.

IX. Conclusion

All of the efforts described above are designed to assist operational personnel in conducting attacks against TBM elements. The identification of specific areas and points, graphically displayed and immediately accessible for pre-planned or time-critical attacks, is the intelligence task. The specific manner in which elements are dealt with is essentially an operational decision based upon available resources and other intelligence information which may have an impact on whether a target is attacked immediately in a time-critical fashion, placed on a target list for the next day's ATO, or further reconnaissance tasked for a variety of reasons. All of these options are discussed in section V and the reader is encouraged to revisit the issue based on the above process.
