Preface and Acknowledgments

At least for the U.S. military, precision aerospace capabilities appear to have become the *sine qua non* for applying force in the defense of national interests. Consequently, airmen have an obligation to study the relationship between precision and warfare. This paper examines a key doctrinal assertion about that relationship, and I hope it generates a lively discussion that ultimately strengthens aerospace doctrine and its influence over future military strategies.

I would like to thank Dr. Philippe Loustaunau at the Institute for Defense Analysis (IDA) for his friendship, support and encouragement as an informal advisor in the development of this paper. His probing questions, expertise and our spirited conversations over the nearest white board ultimately helped me develop my own ideas more effectively. I would also like to thank Mr. Michael Leonard, the Director of IDA's Strategy, Forces and Resources Division (SF&RD), for sponsoring this fellowship opportunity and for providing an outstanding environment in which to do this research. He and his staff made this fellowship experience highly rewarding by inviting me to participate in other studies and graciously including me in on division social activities.

Most of all, I thank my wife Diane. Despite being a full-time mom to our twelve-, nine- and five-year-old children, and despite having carried and delivered beautiful twin girls in February, she still found time to discuss this research, review drafts and generally provide unwavering support and encouragement to me. She is a remarkable woman.

Abstract

Air Force Basic Doctrine asserts that the precise application of force can reliably generate desired, discriminate effects at the strategic level of war. A deconstruction of that assertion reveals three necessary assumptions: the ability to clearly define desired discriminate effects at the strategic level of war, the ability to trace the desired discriminate effects back to a triggering action, and the ability to ensure that the actual effects generated by the triggering action are only the discriminate ones being sought.

This paper presents evidence that these assumptions suffer from important conceptual weaknesses that are amplified when examined from the perspective of nonlinear and complex systems. Further evidence suggests that technological fixes will neither resolve these weaknesses nor produce the strategic efficiencies implied by the doctrinal concept. In fact, such fixes could increase the potential for small errors to combine in unexpected ways to create a system accident, where outcomes diverge in significant and undesirable ways from the intended discriminate strategic effect.

This paper cautions against using the term “precision” in ways that imply congruency between technology and war, and recommends that doctrine clearly differentiate technical exactness from strategic correctness. It concludes that effect-based approaches can foreclose adversary option sets with far more reliability than compelling specific, predetermined behaviors, and it emphasizes the need to ensure that adaptation remains a fundamental feature of any effects-based concept.

The Author

Lieutenant Colonel Timothy J. Sakulich is a country program director at the Defense Security Cooperation Agency, Office of the Secretary of Defense, Arlington, Virginia. Lieutenant Colonel Sakulich was a distinguished graduate of the U.S. Air Force Academy in 1984. He then attended North Carolina State University where he earned a MS degree in applied mathematics. He is an experienced military operations research and systems analyst whose assignments have included positions at Headquarters Air Force Logistics Command, the San Antonio Air Logistics Center, and the Joint Staff. This paper was written during his tenure as a National Defense Fellow at the Institute for Defense Analysis in Alexandria Virginia.

I. Introduction

*[The] art of commanding aerospace power lies in integrating systems to produce the exact effects the nation needs.*¹

AF Vision 2020

In his book, *Technology and War*, distinguished military historian and author Martin Van Creveld discusses the tight interrelationship between war and technology: “War is permeated by technology to the point that every single element is either governed by or at least linked to it...it is no less true that every part of technology affects war.”² This relationship is particularly acute for airman as a result of what John S. Foster and former Air Force Chief of Staff General (Ret.) Larry D. Welch call a revolution in precision that permeates weapons, navigation, surveillance, and command and control.³ The integration of precision technologies into aerospace systems has enabled order-of-magnitude improvements in combat efficiency (i.e., combat aircraft losses, tonnage per target, and overall combat losses).⁴ Not surprisingly, precision technologies have greatly influenced the airman’s view of war, and *Air Force Basic Doctrine* embraces precision in part because it increases the efficiency of aerospace force application.⁵

However, AFDD 1 goes much further when it asserts that the precise application of force can reliably generate desired, discriminate effects at the strategic level of war. In doing so, AFDD 1 extends the role of precision well beyond quantitative and engineering measures of efficiency, and beyond an earnest desire to limit collateral damage. AFDD 1, in fact, implies something far more fundamental about the nature of war. This paper examines whether it is reasonable to build a war-fighting concept around such an idea, henceforth referred to as *strategic precision engagement*.

Doctrine appears to be in conflict with itself on this matter. AFDD 1 asserts, “war is a complex and chaotic human endeavor. Human frailty

2...Precision Engagement at the Strategic Level of

and irrationality shape war's nature. Uncertainty and unpredictability—what many call the 'fog' of war—combine with danger, physical stress, and human fallibility to produce 'friction,' a phenomenon that makes apparently simple operations unexpectedly, and sometimes even insurmountably, difficult. Uncertainty, unpredictability, and unreliability are always present."⁶ The juxtaposition in doctrine, of a core competency of airpower built around precision application of force seeking discriminate outcomes at the strategic level of war on the one hand, versus Clausewitzian friction on the other, appears contradictory.

Doctrinal contradictions matter because doctrine is supposed to represent "a statement of officially sanctioned beliefs...a common set of understandings on which airmen base their decisions."⁷ Moreover, doctrine's influence is not confined to the aerospace professional but ultimately affects national strategic choices. As Barry Posen puts it, doctrine "is the subcomponent of grand strategy that deals explicitly with military means."⁸ Yet despite the potential significance of the internal conflict, it may not be possible to fully resolve it and it is not the goal of this paper to attempt to do so. Instead, the author embraces Michael Handel's perceptive conclusion that tensions and contradictions are inherent in military theory and doctrine. In his book, *Masters of War*, he argues that "the strategist's objective is not necessarily to resolve or eliminate every anomaly, but rather to understand why wrestling with these questions can bring better insight into the nature of war."⁹

This paper will explore how USAF doctrine connects precision engagement to the strategic level of war, deconstruct that relationship to reveal key assumptions, and explore the problem using insights from the study of nonlinear and complex adaptive systems. From this it will assess the potential for a technological solution and propose ways to avoid the pitfalls inherent in strategic precision engagement.

II. Aerospace Precision and Strategic Precision Engagement

Above all, PGMs connect political objectives to military execution with much greater reliability than ever before. The political leader can have far greater confidence that discrete objectives can be met and can thus gain broader latitude in formulating the overall objective. This is not just a change in air power or even in military power; it is a fundamental change in warfare.¹⁰

General Charles Boyd

Precision and Aerospace “Efficiencies”

It is clear that precision technologies have allowed airpower to achieve unprecedented efficiencies in the application of raw combat power. For example, during the execution of the Combined Bomber Offensive, it took 3000 sorties dropping 9000 bombs with a circular error probable of 3000 feet to destroy a 60-by-100 foot target.¹¹ Today, the same target can be obliterated with a single precision guided weapon delivered by a Joint Direct Attack Munition (JDAM) delivered by a single B-2A sortie “with FedEx-like reliability” launched from thousands of miles away.¹² Doctrine calls this the ability to “mass effects” without having to “mass forces.”¹³ As Colonel Phillip Meilinger noted in his pamphlet *10 Propositions Regarding Airpower*,

Precision air weapons have redefined the meaning of mass.... The result of the trend towards ‘airshaft accuracy’ in air war is a denigration in the importance of mass. PGMs provide density, mass per unit volume, which is a

4...Precision Engagement at the Strategic Level of

more efficient measurement of force. In short, targets are no longer massive, and neither are the aerial weapons used to neutralize them. One could argue that all targets are precision targets—even individual tanks, artillery pieces, or infantrymen. There is no logical reason why bullets or bombs should be wasted on empty air or dirt. Ideally, every shot fired should find its mark.¹⁴

In addition to their raw efficiencies, precision technologies also enable aerospace forces to reduce first-order “unintended” casualties and collateral damage that might otherwise result from attacking military targets.¹⁵ Airpower theorist and author Richard Hallion believes that precision weapons provide decision makers with a source of confidence when considering the use of force “in circumstances where so-called ‘collateral damage’ would be either unacceptable or call into question the viability of continued military action.”¹⁶ As a result, Hallion continues, “decision-makers have a freedom to use military force closer to non-combatant-inhabited areas in an enemy homeland (or in enemy-occupied territory) than at any previous time in military history.”¹⁷ Thomas Keaney, a co-author of the Gulf War Airpower Survey and current head of the Johns Hopkins Foreign Policy Institute, believes “with all the political restraints on the air campaign...precision systems are what made the victory in Kosovo possible.”¹⁸ Of course, the flip-side of this freedom is what John Foster and Larry Welch describe as an emerging political *imperative* to use precision weapons whenever possible in order to reduce casualties and collateral damage.¹⁹

Precision and “Discriminate Effects”

The 1995 publication of *Joint Vision 2010* gave precision technologies a more formal role in military planning when it defined precision engagement as one of four enabling operational concepts for future joint warfare. *Joint Vision 2010* described it as “a system of systems that enables our forces to locate the objective or target, provide responsive command and control, generate the desired effect, assess our level of success, and retain the flexibility to reengage with precision when required.”²⁰ Five years later, *Joint Vision 2020* reaffirmed precision engagement and provided a more formalized definition: “Precision

Engagement is the ability of joint forces to locate, surveil, discern, and track objectives or targets; select, organize, and use the correct systems; generate desired effects; assess results; and reengage with decisive speed and overwhelming operational tempo as required, throughout the full range of military operations.”²¹ Neither document sought to provide detailed descriptions of the systems required to achieve precision engagement, but both documents clearly characterized precision engagement as an outgrowth of technology, and both intended to frame debates over joint force requirements and capabilities. Both documents focus on the operational level of war and both characterize precision engagement to mean more than simply avoiding collateral damage but about taking specific actions to achieve well-defined outcomes.

Air Force Doctrine Document 1 (AFDD 1), *Air Force Basic Doctrine*, declares that “air and space forces today contribute directly” to achieving the joint vision concept of precision engagement.²² AFDD 1 also identifies precision engagement as a core competency of aerospace power. However, AFDD 1 goes well past the joint vision definitions when it claims an ability to generate “discriminate effects” directly at the strategic level of war:

Increasingly, air and space power is providing the “scalpel” of joint service operations—the ability to forgo the brute force-on-force tactics of previous wars and apply discriminate force precisely where required. Precision engagement is the ability to command, control, and employ forces to cause discriminate strategic, operational, or tactical effects. The Air Force is clearly not the only Service capable of precise employment of its forces, but it is the Service with the greatest capacity to apply the technology and techniques of precision engagement anywhere on the face of the earth in a matter of hours or minutes.²³

The ability to achieve *discriminate effects* at the *strategic level* through *precise application of force* seems appealing because it promises confident efficiencies and proportionality in time, lives and national treasure in the pursuit of national objectives. It suggests a degree of control that would allow us to manage a conflict, bending the adversary to our will with minimal casualties and collateral damage to either the

6...Precision Engagement at the Strategic Level of

adversary or us. It is particularly appealing in coercive situations involving more limited objectives, “one that doesn’t necessarily call for the ultimate destruction of an enemy regime, but instead changes an adversary’s ‘mind set.’”²⁴ Major General (select) David Deptula, a chief architect of the Gulf War air campaign argues, “People have come to think...over tens of thousands of years of conflict that it’s all about breaking things and damaging....There are effects that we can achieve today through other means than absolute destruction....How can the U.S. military, and, more specifically, the Air Force do that? Through the use of precision guided munitions delivered over stand-off ranges.”²⁵

Thus, *Air Force Basic Doctrine* extends precision well beyond quantitative and physics measures of efficiency and well beyond the desire, or even imperative, to limit collateral damage. Doctrine clearly connects precision action to discriminate strategic effects. Underlying this connection is a set of three key assumptions needed to actually achieve strategic precision engagement.

III. Strategic Precision Engagement: The Underlying Assumptions

Modern governments, in guiding their country through a war, can draw on vast masses of data and avail themselves of day-to-day, or even hour-by-hour, reports from their far-flung intelligence systems. Nonetheless, some of their key decisions have to be taken in the face of great uncertainties. But government leaders frequently fail to acknowledge these uncertainties or to take them into account in their decisions. Instead, they often implicitly assume answers to questions that they have never examined.²⁶

—Fred Charles Iklé

The ability to achieve discriminate effects at the strategic level of war through the precise application of forces rests on three necessary assumptions: the ability to define desired discriminate effects at the strategic level of war, the ability to trace the desired discriminate effects back to a triggering action, and the ability to ensure the *actual* effects generated by that action are only the discriminate ones being sought. To analyze each in turn, it is first necessary to examine a subtle yet important distinction between technical precision and underlying accuracy.

Exactness Is Not Equivalent to Correctness

John Foster and Larry Welch assert “precision has to do with a broader range of capabilities than just the spatial accuracy of delivery.”²⁷ Unfortunately, there is no formal definition of precision in the DoD Dictionary or Air Force doctrine. Miriam-Webster’s *Collegiate Dictionary* defines precision as:

8...Precision Engagement at the Strategic Level of

1. the quality or state of being precise: EXACTNESS
- 2a. the degree of refinement with which an operation is performed...compare ACCURACY²⁸

In contrast, it defines accuracy as:

1. freedom from mistake or error: CORRECTNESS
- 2a. conformity to truth or to a standard or model : EXACTNESS
- 2b. Degree of conformity of a measure to a standard or a true value – compare PRECISION²⁹

In other words, *precision* is to *accuracy* as *degree of refinement* is to *underlying truth*. More plainly, a calculation performed to many decimal places might well be described as *precise*, but can only be *accurate* if the equations being used conform to the underlying truth of what is being modeled. This distinction, though subtle, is essential to understand what is required to achieve strategic precision engagement.

Clearly, precision engagement is founded on the degree of refinement that technology provides. Notwithstanding human and technological errors that result in missed targets, technology has profoundly impacted the degree of refinement possible in munitions delivery. AFDD 1 states that “increasingly, air and space power is providing the ‘scalpel’...[to] apply discriminate force precisely...”³⁰ Moreover, computing power has allowed unprecedented ability to process staggering amounts of data through detailed models of physical systems and infrastructure that enable aerospace targeteers to establish very precise aim points.

But USAF doctrine clearly means more than degree of refinement when it states that “precision engagement is the ability to command, control, and employ forces to cause discriminate...effects....It is the effect, rather than forces applied, that is the defining factor.”³¹ Underlying this statement is an assumption that hitting the precisely established aim point (i.e., exactness) will in fact generate the desired discriminate effect (i.e., correctness). Elsewhere AFDD 1 describes “the precise, coordinated application of the various elements of air, space, and surface forces [exactness] which brings disproportionate pressure on enemy leaders to comply with our national will [correctness].” Under the tenets of flexibility and versatility, AFDD 1 prescribes “the swift, massive, and

precise application of air, space, and information power” for parallel strategic operations.³² Clearly refinement in weapons delivery and computing power is not sufficient to claim discriminate outcomes. The degree of selectivity and control implied by these statements demands knowledge of the underlying truths or correctness that connect the precise application of force to discriminate strategic effects.

The point is that when AFDD 1 talks about precision, it intermingles exactness and correctness. It muddies the difference between capabilities that can be verified through direct technical experimentation and capabilities that can only be *postulated* from airpower theories not amenable to direct proof and from extrapolation of a known past to an unknown future.

A Conceptual Model

Figure 1 illustrates a conceptual model for analyzing strategic precision engagement. This model provides a basic structure for discussing the assumptions of strategic precision engagement. It is intentionally generic, in order to avoid the maxims and metaphors that Peter Faber cites as “pathologies” of airpower theory.³³

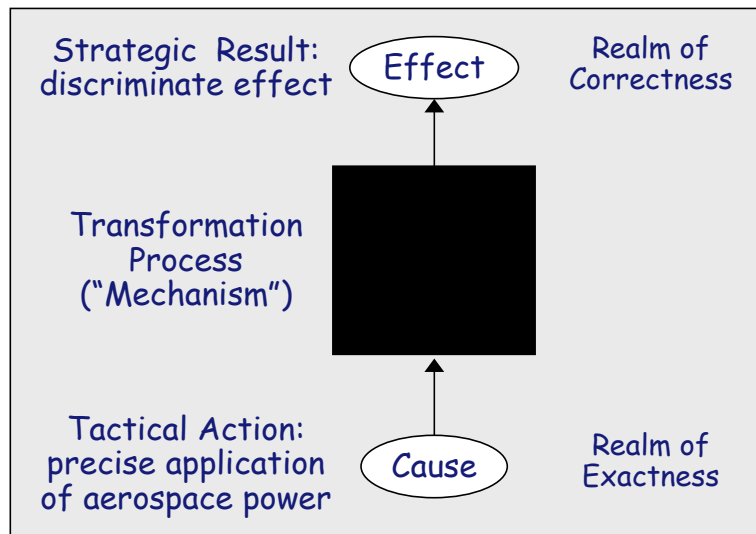

Figure 1. Black Box Linking Cause to Effect

Defining the Desired Discriminate Effects

It does not make sense to talk about discriminate effects unless those effects are clearly defined in advance. If for no other reason, the decision maker must communicate the discriminate outcome to planners who must develop the means to achieve it. Foster and Welch argue the need for “precision of purpose and objectives” to ensure the most appropriate application of high-technology weapons.³⁴

Just as important, the term “discriminate effects” implies something far less than the cataclysmic collapse of the adversary. Indeed, strategic precision engagement derives much of its appeal by promising limited political objectives through coercive but not catastrophic measures. While in some cases the political leadership may seek the cascading collapse of the adversary, it does not seem reasonable to characterize such an outcome as discriminate. Achieving precision engagement at the strategic level of war requires an explicit description of effects that support political outcomes expressed as limited objectives.

Aerospace commanders have always sought to define and achieve effects. But more recent concepts such as “effects-based targeting” and “effects-based operations” have helped mature the discussion of how best to define effects relative to aerospace means.³⁵ The CINCs in particular welcome these efforts. In a recent conference on aerospace power, General Anthony Zinni, former commander-in-chief, US Central Command, espoused the belief that effects-based approaches are valuable because they “force[s] senior commanders and political leaders to define what they want to accomplish.” He illustrated his point with the example of OPERATION DESERT FOX and said effects-based thinking helped decision makers develop a realistic definition of what *could* be achieved—in this case a narrower effect of delaying rather than destroying Iraqi missile programs. Gen Zinni credited this approach with enabling planners to design operations that achieved the political objectives.³⁶

Interestingly, while *Air Force Basic Doctrine* refers to tactical, operational and strategic effects, synergistic effects, parallel effects, decisive effects, and overwhelming effects, it fails to actually define effects.³⁷ The closest to an actual definition appears in a discussion of attacking enemy centers of gravity (COGs) where the doctrine states, “Strategic attack objectives often include producing effects to demoralize

the enemy's leadership, military forces, and population, thus affecting an adversary's capability to continue the conflict."³⁸

AFDD 2-1, *Air Warfare*, published in January 2000, more than two years after AFDD 1, actually does provide some definitions. It states that effects are "the operational- or strategic-level outcomes that [the broad, fundamental, and continuing activities of aerospace power] are intended to produce."³⁹ It further states that a "strategic effect is the disruption of the enemy's strategy, ability, or will to wage war or carry out aggressive activity through destruction or disruption of their COGs or other vital target sets, including command elements, war production assets, fielded forces, and key supporting infrastructure."⁴⁰

The draft of AFDD 2-1.2, *Strategic Attack*, describes effects as "distinctive and desired results" and says they "may occur at all levels of war."⁴¹ It specifically relates effects to "physical or psychological outcomes...[that] change the adversary's behavior or exceed its willingness to resist" and counsels that "careful analysis" is required to ensure effects contribute to the overall objectives of the National Command Authority and Joint Force Commander.⁴²

Further insights into the nature of effects and the challenges of defining discriminate effects are emerging from a recent study on effects-based operations conducted by the Joint Advanced Warfighting Project (JAWP) at the Institute for Defense Analyses (IDA). This study describes four classes of effects: desired effects on the enemy's capabilities, desired effects on enemy assessments and actions, undesired effects, and unexpected effects.⁴³ The first three categories offer important insights into what is required to describe discriminate effects; this paper will address the fourth category during the discussion on boundedness.

The JAWP study notes that certain effects depend entirely on blue action whereas others depend on how the enemy *reacts* to blue's actions.⁴⁴ Physical destruction of surface-to-air missile sites means the enemy no longer has the option of launching missiles from those particular sites—an effect on the enemy's actual capability that resulted solely from blue action. At some point, the enemy may decide to stop using his remaining launchers for fear that they, too, will be destroyed. In that case, blue's action has had an effect on the enemy's assessment of the situation and his

12...Precision Engagement at the Strategic Level of

actions. The former effect is relatively permanent and amenable to direct measurement—e.g., traditional battle damage assessment. One must use indirect means to infer the latter type of effect. Logically, such effects persist as long as the enemy's assessment remains unchanged. The JAWP study notes that these two types of desired effects may change enemy options and actual behaviors but pointedly cautions against assuming either type necessarily changes the enemy's underlying *will*.

The second contribution of the JAWP study is the need to explicitly account for undesirable effects, which the study argues, "are usually easier to understand after the fact than to predict."⁴⁵ Neither AFDD 1 nor AFDD 2-1 explicitly address the possibility of undesirable effects but the draft version of AFDD 2-1.2 promises to fill this gap with its discussion of collateral effects:

Commanders should be aware of possible collateral effects from strategic attack operations. These are unintentional or incidental direct or indirect effects causing injury or damage to persons or objects. Besides studying possible first-order collateral effects, evaluation of potential collateral effects should include consideration of second- and third-order systemic effects. For example, destroying utility systems providing power to the enemy's military C2 network may also have a debilitating effect on health and public services supporting the civilian population. These negative indirect effects can work against achieving friendly force objectives and activate a friendly COG (e.g., public opinion) against a military operation...⁴⁶

Historian Richard Hallion provides an excellent example of an undesirable effect. He notes that "well-publicized attacks against bridges in downtown Baghdad, coupled with a precision attack against the Al Firdos command and control bunker that killed several hundred individuals using it as a shelter, generated a political reaction that included shutting down the strategic air campaign against Baghdad for ten days. This occurred despite clear evidence that the Hussein regime was trying to reconstitute key leadership functions destroyed or degraded by previous attack."⁴⁷ Based on this example, seems unreasonable to describe an effect as discriminate if its dominant components are undesired.

In sum, a necessary assumption underlying precision strategic engagement is the ability to define effects discriminately. Whereas some effects are direct and can be described in terms of raw capabilities; others are indirect and must be described in terms of enemy choices. Moreover, the possibility of undesirable effects requires an explicit differentiation between what the decision maker wants, what he does not want but can accept, and what he cannot accept at all. This will not be simple even in cases of large-scale threats to US vital interests. General John Jumper compares the simplicity of Eisenhower's mission in the European Theater of Operations to that of the coalition forces in DESERT STORM where "we had 26 pages of limits, concerns and caveats."⁴⁸ How much more challenging will it be to define the full spectrum of desired and undesired effects in cases involving far more limited objectives and taking place in a complex strategic environment? Achieving precision engagement at the strategic level of war assumes that this is possible.

Tracing Effects Back to Causes

In a recent article in *Aerospace Power Journal*, Col Phillip Meilinger notes that the history of airpower has in some sense been a search to understand the connection between aerospace action and strategic effect. He notes that from the airpower's earliest days, various theories and models have attempted to define, implicitly or explicitly and to varying degrees, those "mechanisms" or linkages.⁴⁹ Yet Faber argues "given the over-concentration by early theorists on the mechanics of targeting, it should be no surprise that the causal relationship between aerial attacks and political outcomes remains murky. In fact, a clear exposition of this relationship remains the Holy Grail of airpower theory."⁵⁰ Unfortunately achieving strategic precision engagement depends on that clear exposition.

Foster and Welch argue "in recent years, physics and other sciences have contributed extensively to an emerging national-security goal that 'for every desired battlefield outcome there should be a precise and well-defined action.'"⁵¹ *Air Force Basic Doctrine* extends this causal relationship beyond battlefield outcomes and specifically refers to strategic outcomes. It states "aerospace forces can often strike directly at key target sets that have strategic results, without having to go through the process of drawn-out attrition at the tactical level of war. Analyzing the enemy for such critical targets is a fundamental part of aerospace

14...Precision Engagement at the Strategic Level of

warfare.”⁵² In the words of airpower expert Edward Luttwak, “all the strategy [for airpower] lies in the selection and prioritization of targets.”⁵³ Strategic precision engagement assumes the airpower planner is able to trace the discriminate strategic effect back to some specific tactical action—i.e., a target—that generates it. This black box in Figure 1 is essentially a representation of that relationship.

AFDD 2-1, Air Warfare emphasizes the need to articulate the connections between cause and effect, noting that Joint Air Operations Plans “should include a desired outcome, target set, and a mechanism for achieving the desired outcome” and that there should be a “demonstrated link between [a] target’s destruction and the achievement of aerospace and overall military objectives.”⁵⁴ *AFDD 2-1* cautions that “failure to properly analyze the mechanism that ties tactical results to strategic effects has historically been the shortcoming of both airpower theorists and strategists.”⁵⁵ The important point here is similar to one that Major John Carter makes in *Airpower and the Cult of the Offensive*, where he warns not to confuse the executability of an aerospace operations plan with the effectiveness of that plan.⁵⁶

Former Air Force Chief of Staff General Ronald Fogelman illustrated the challenges of determining mechanisms when he wrote, “It is easy to quantify the effects of air power at the tactical level; for example, how many trucks and how many tanks are destroyed. These are results we can measure and compare with results from other weapons. It is difficult to show the cause-and-effect of air power when it is used strategically and innovatively.”⁵⁷ Other airpower authorities have argued “the Air Force’s increasing ability routinely to hit targets with great accuracy has not been matched by a commensurate understanding of exactly which targets to hit to achieve specific outcomes—what is now called ‘effects-based targeting.’”⁵⁸ Obviously this situation must change if aerospace power is to achieve discriminate strategic effects that are limited and intended to coerce rather than completely annihilate an enemy.⁵⁹ This is why strategic precision engagement assumes that the black box in Figure 1 exists and that there is some algorithm that enables aerospace planners to trace desired discriminate effects back to their triggering actions.

Uncertainties in Ensuring Desired Effects

Even the most enthusiastic proponents of high-technology approaches to warfare do not predict that future commanders will have *perfect* battlespace knowledge.⁶⁰ Since strategic precision engagement cannot assume perfect information, it will depend on some approximation of the relationship depicted in Figure 1. The question is whether the uncertainties introduced by such an approximation are acceptable relative to the desired discriminate effect.

Consider the example of Operation Allied Force. General Wesley Clark, Commander-in-chief, U.S. European Command during Operational Allied Force, argues that NATO's political leadership was very sensitive to casualties and collateral damage. He felt that uncertainties came to dominate even "routine" battlefield targeting decisions: "We needed to know what was inside of the trucks. When we couldn't find out, we stopped bombing trucks. We needed to know what was inside of the buildings. When we couldn't find out, we stopped bombing buildings. We needed to know what was under the camouflage net. When we couldn't find out, we stopped bombing the camouflage nets."⁶¹ The "exactness" of the weapons was not the main issue. The issue was whether striking a particular set of geographic coordinates would produce an effect that was *acceptable*, even if it wasn't precisely the effect that was *intended*. Nobody wanted an Allied Force equivalent to the Al Firdos bunker; the political fallout might have had serious negative consequences for the alliance as a whole.

Strategic precision engagement can accept the uncertainties of imperfect information as long as it is possible to ensure that, given a good approximation of the black box, the differences between *actual* effects and the intended discriminate effects will be predictably small in terms of time, resources, lives and overall political capital. This is why strategic precision engagement assumes an ability to ensure the actual effects generated by that action are only the discriminate ones being sought.

An Operationalized View of Uncertainties

The previous section describes a key assumption regarding the nature of uncertainties in strategic precision engagement. It notes that the concept does not require absolute elimination of uncertainties. This

section looks at those remaining uncertainties from the perspective of the decision makers and planners who must interact to implement strategic precision engagement.

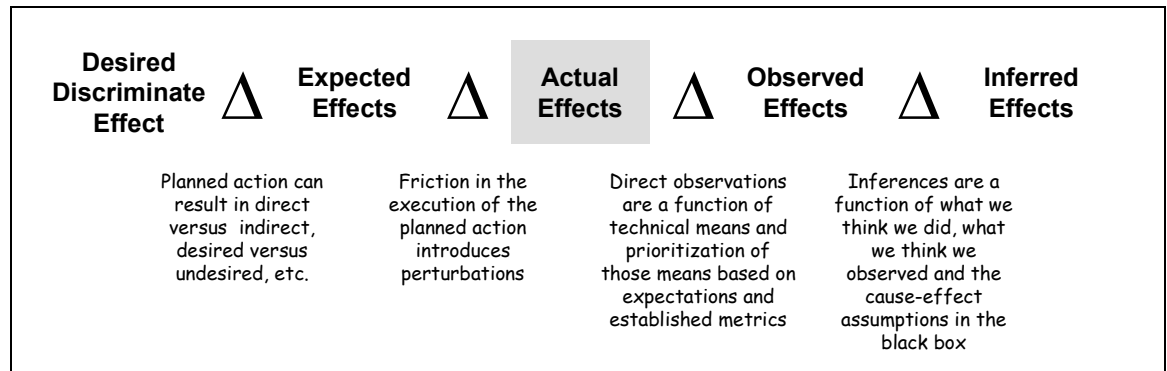

Figure 2. Uncertainties in Strategic Precision Engagement

Figure 2 shows that there are uncertainties in the process of narrowing the difference between what decision makers desire and what planners expect to occur. When the decision maker specifies the discriminate effect, the planners use their current approximation of the black box algorithm to create a candidate tactical action. Reversing the black-box algorithm may reveal that the candidate action will generate effects not considered by the decision maker in his original decision. Clearly the way to reduce uncertainty here is to give the decision maker an opportunity to refine his decision on the desired effects and repeat the process until the decision maker is satisfied that he has made an informed choice. This

does not guarantee complete closure but may provide confidence that the remaining uncertainties are acceptably small.

There are uncertainties as result of either imperfect knowledge or imperfect execution. Imperfect knowledge may lead to a difference between observed action and effect and the actual action and effect. A comprehensive capture and analysis of all directly observable data is virtually impossible; so planners must develop data collection priorities based on the black box approximation, the planned action and the expected effects. Any data not captured or analyzed is a potential source of uncertainty regarding the action as it *actually* occurred and the full range of subsequent effects as they *actually* occur. Second, unless we can assume away weapons malfunctions, operator error, etc..., uncertainties will enter into the technical execution of the planned action.

Finally, one of the most important sources of uncertainty derives from the process of developing inferences from direct observations. Direct observation can confirm that a weapon hit its aim point or that a bridge is physically destroyed. However, some important strategic effects are not amenable to direct measurement. Aerospace authority and author Barry Watts points out that “one can measure temperature or mass readily enough with a single number, but social utility or the second-order consequences of wartime decisions years afterwards may be another matter entirely given the spatial-temporal distribution of the relevant information and the limits of human cognition.”⁶²

Inferences are a function of what we *think* we did, what we *think* we observed and what we *think* to be true regarding the cause-effect relationships of the black box. When the inferred result matches the expected result, planners and decision makers are likely to accept their approximation of the black box algorithm as valid, potentially reinforcing latent biases. If there are discrepancies between the expected effect and the inferred effects, planners might ignore the data that caused the contradiction as an anomaly or data hiccup, augment the algorithm with a new parameter that explains the discrepancy (what positivists might call a “hidden variable”), or scrap the old algorithm and pick a new one all together. Such judgments are crucial since inferences feed into subsequent decisions. If Iklé is correct when he warns of the tendency of warring governments to “implicitly assume answers to questions... never examined,” then decision makers and planners must take extra care to guard against this potentially dangerous source of uncertainty.

Summary

The central concern here is that *Air Force Basic Doctrine* blurs the distinction between exactness and correctness when it refers to precision. In effect, doctrine suggests technical improvements in the exactness of weapons result in ipso facto improvements in the correctness of using these weapons to achieve desired discriminate effects. Successful strategic precision engagement clearly depends on both exactness and correctness.

In deconstructing strategic precision engagement into its underlying assumptions, there are difficulties with those assumptions. Insights from the study of nonlinear and complex systems will cast even further doubt on the reasonableness of these assumptions.

IV. Insights from the Study of Complex Adaptive Systems

“In war the chief incalculable is the human will.”

—B. H. Liddell Hart

The study of nonlinear and complex interactive systems offers a number of insights into the concept of strategic precision engagement. This chapter reviews key characteristics of such systems and discusses the implications for achieving precision engagement at the strategic level of war.

Nonlinearity and Complex Adaptive Systems

Physical systems are either linear or nonlinear. Linear systems exhibit proportionality between input and output. Small changes in the value of an input will result in proportionately small deviations of the output. Linear systems also exhibit the property that the whole is equal to the sum of its parts. Any system that does not exhibit both properties is nonlinear.⁶³ In nonlinear systems, it is possible for small perturbations in

system inputs to cause dramatic changes in system outputs and the system as a whole can be quite different than the sum of its component parts.

In his book *Chaos: Making a New Science*, James Gleick points out that seemingly simple systems can produce highly nonlinear behaviors. One example, among many he describes is a well-known population growth model known as the logistic equation. This simple equation consists of one variable representing the population size, and one control parameter used to represent how the population responds to its environmental conditions. Over certain ranges of values, the tiniest of changes in the control parameter will dramatically affect the behavior of the system.⁶⁴ The logistics equations illustrate that nonlinear systems can be highly sensitive to tiny errors in estimating control parameters, including those introduced when real world analog values are converted into finite digital representations for the sake of high-speed computation. Gleick notes that such systems may be completely deterministic (i.e., not random) and yet defy computability and long-term prediction.

Detailed prediction becomes far more complicated when the number of system components multiplies. James Maxfield defines a complex adaptive system as an “open-ended system of many heterogeneous agents who interact non-linearly over time with each other and their environment and who are capable of adapting their behavior based on experience.”⁶⁵ He describes how the overall output of such systems cannot be predicted through decomposition into the system’s component parts and decision rules because these systems can exhibit self-organization, evolutionary trajectories, co-evolution and punctuated equilibrium.⁶⁶ Robert Jervis explains that in such systems “strategies depend on the strategies of others.” Each individual action changes the environment in which subsequent system interactions take place. The collective “behavior” of such systems can be very complex and can defy detailed prediction.

The Black Box Involves Nonlinearity and Complex Interactions

That nonlinearities are inherent in warfare is not a new idea. Author Alan Beyerchen notes that Clausewitz acknowledged nonlinearity, even though he did not term it such. For instance, Clausewitz writes in *On War*, “the same political object can elicit differing reactions from different peoples, and even from the same people at different times.... Between two

peoples and two states there can be such tensions, such a mass of inflammable material, that the slightest quarrel can produce a wholly disproportionate effect—a real explosion.”⁶⁷ More recently, Watts used non-linearity to reconstruct the Clausewitzian concept of general friction to include “the structural nonlinearity of combat processes which can give rise to the long-term unpredictability of results and outcomes by magnifying the effects of unknowable small differences and unforeseen events (or, conversely, producing negligible results from large inputs).”⁶⁸

AFDD 1 not only acknowledges the existence of nonlinearity, it characterizes it as something to be exploited: “The proper application of a coordinated force can produce effects that exceed the individual contributions of the individual forces employed separately.”⁶⁹ The synergy described by AFDD 1 can only be possible if the black box cause-effect relationship is nonlinear. Moreover, the effect must be the product of multiple interactions within the black box. In assessing the impact of airpower during the Gulf War, one military planner commented that “If there is a lesson to be gained from the Desert Storm campaign, it is that airmen should carefully examine their linkages between all target sets and the intended effect on the enemy.”⁷⁰ Linkages represent the presence of interactions that are a defining characteristic of complex systems.

Assuming that war is nonlinear and made up of complex interactions, the descriptive characteristics of nonlinear and complex systems should lead to skepticism over the reasonableness of the assumptions described in the previous chapter. First, underlying nonlinearities increase uncertainties about the full spectrum of effects that may occur subsequent to an action. According to Jervis, “In a system, the chains of consequences extend over time and many areas: the effects of action are always multiple.”⁷¹ “In politics, connections are often more idiosyncratic, but their existence guarantees that here too most actions, no matter how well targeted, will have multiple effects.”⁷² Alvin and Heidi Toffler point out, “The greater the interdependence, the more countries are involved and the more complex and ramified the consequences. Yet interrelationships are already so tangled and complex that it is nearly impossible for even the brightest politicians and experts to grasp the first- or second-order consequences of their own decisions.”⁷³ Planners and decision makers will be hard-pressed to define effects with a high degree of specificity—what is desired and what is not desired—in a realm where we may not even foresee the possibility of a particular evolutionary direction.

Second, Jervis cautions against assuming we can predict behavior of the whole through a detailed examination of the component parts. That doesn't mean detailed analyses of individual components are pointless—detailed analyses offer insights that might not otherwise be known. In fact, organizations such as the Joint Warfare Analysis Center exist for that very purpose and can perform highly detailed and accurate models of adversary infrastructure to assist joint force commanders with campaign planning.⁷⁴ However, one cannot conclude that a detailed deconstruction will allow prediction of discriminate aggregate behavior and it is this aggregate behavior that is important at the strategic level of war. This makes discovery of a tight cause-effect linkage from tactical action to strategic effect highly problematic.

Third, when generating effects at the strategic level of war, perturbations matter. Unfortunately, there are many sources of perturbations that are outside the direct control of military decision makers. In his classic study of the national security decision making, Graham Allison found that vital decisions may not involve rational, value-optimizing, synchronized choices across all instruments of power. One reason for this is that large organizations tend to deal with the unfamiliar by appealing to in-place standard operating procedures. These procedures contain built-in assumptions that, unfortunately, are not always readily apparent to those executing the procedures.⁷⁵ The assumptions are hidden, not subjected to scrutiny, and may or may not apply black box at hand. Yet if any of these assumptions are invalid, the prescribed actions will be based on a black box that is different from the actual black box being used. In effect, this difference introduces a perturbation relative to the action that *would have* been taken had the organization used more “correct” assumptions. Allison also found that the bureaucratic political competition of key policy makers can introduce other perturbations—sometimes as a result of misunderstandings and foul-ups.⁷⁶ On top of all that, external actors can generate inputs or perturbations to the black box that the military cannot control and may not even be aware of. Unfortunately, complexity implies that one cannot reliably predict which perturbations will cause divergence from the intended strategic effect.

Finally, the interactions internal to the black box can change over time, and can change unexpectedly. Jervis notes “politics, like nature, rarely settles down as each dispute, policy, or action affects others and reshapes the political landscape, inhibiting some behaviors and enabling others.”⁷⁷ Individual interactions are not independent but take place

within the context of all the other interactions—each action provides the initial conditions for all subsequent actions. Moreover, Watts notes that the significance of some interactions cannot be known until “individuals are confronted with particular...choices in particular circumstances. Other elements, especially those having to do with long-term consequences, can only be known later in time because of the subsequent contingent choices open to other individuals.”⁷⁸ A linkage once dismissed as insignificant could later become critical. Watts describes this as the “inaccessibility of critical information.”⁷⁹ The net effect is that “initial behaviors and outcomes often influence later ones, producing powerful dynamics that explain change over time and that cannot be captured by labeling one set of elements ‘causes’ and other ‘effects.’”⁸⁰ Van Creveld captured this when he wrote, “The underlying logic of war is, therefore, not linear but paradoxical. The same action will not always lead to the same result.”⁸¹

The problem is that strategic precision engagement wants to have it both ways. It is a view of war that acknowledges and even seeks to exploit nonlinearities against an adversary while simultaneously suggesting that such nonlinearities can be predicted and controlled in ways that produce discriminate outcomes to our benefit. If the black box is characterized by nonlinearity and complex interactions then, as a minimum, we should be doubtful over our ability to guarantee desired discriminate effects. If nothing else, the passage of time represents opportunities for additional perturbations and evolution to occur. The absence of caution could easily lead a mindset that seeks a *fait accompli*, something USMC doctrine effectively warns against:

The *fait accompli* is another potential strategic pitfall. It is immensely attractive to political leaders because it seems neat and clean—even “surgical.” The danger is that many attempted *faits accomplis* end up as merely the opening gambit in what turns out to be a long-term conflict or commitment. This result was normally not intended or desired by those who initiated the confrontation. In 1983, the Argentines assumed that their swift seizure of the nearby Falkland Islands could not be reversed by far-off, post-imperial Britain and that therefore Britain would make no effort to do so. They were wrong on both counts.⁸²

24...Precision Engagement at the Strategic Level of

General John Jumper's put it more succinctly when he said, "Don't ever start anything where the only plan consists of one phase."⁸³

V. Can Technology Provide the Necessary Fix?

A Control-Feedback Loop

The previous discussion reveals weaknesses in the assumptions required by strategic precision engagement to connect precision action to discriminate effects. Still, technology has provided a means of successfully managing and controlling some highly nonlinear processes using control-feedback processes that leverage short-term predictability to achieve longer term outcomes. Alvin Saperstein, writing in *American Scientist*, suggested that such control might be possible in a strategic sense:

The similarity between the calculated behavior of complexity-dominated systems and the behavior of sociopolitical systems in the real world gives considerable credence to the idea that the real world is dominated by deterministic rules and that the observed contingency is due to the occasional sensitivity of the real system to minor, but always present, random perturbations. This paradigm is quite different from that which supports the observed contingencies of the world on an underlying stochastic foundation. The choice between the two approaches to sociopolitical reality is not purely academic but has profound practical consequences. Both paradigms rule out the possibility of long-term prediction, but the complexity scheme does allow for short-term prediction and thus offers the possibility of control.⁸⁴

Thus, there is some optimism over technology's ability to perform highly accurate observations, conduct rapid analysis, provide *short-term* prediction and guide precision actions. Can technology operationalize a construct built on short-term control-feedback that approximates precision engagement at the strategic level of war?

Technology Opportunities

While *Air Force Basic Doctrine* does not claim technology will eliminate friction in war it does cite technology as a positive factor in reducing friction's effects.⁸⁵ There are a number of reasons for technological optimism, including the phenomenal advances in the means available to gather and process information over the past decade. Vice CJCS Admiral Owens provides a representative perspective. In his book, *Lifting the Fog of War* he argues the case for a revolution in military affairs built on a system of systems that combines the technologies of battlespace awareness, C4I and precision force. He believes current technology demonstrates the potential to give military commanders a real time, "omniscient view of the battlefield" allowing them to "'see' virtually everything of military significance," regardless of weather, terrain and in day or night.⁸⁶ At the same time Owens does not expect the system of systems to provide perfect knowledge or ensure perfect execution, but that it could provide a critical relative advantage over less technologically-enabled opponents.⁸⁷ Other authorities envision the possibility of "dominant battlespace knowledge." Martin Libiki expects information technologies to provide commanders with an "unprecedented level" of awareness of the conditions surrounding their decisions.⁸⁸ David Alberts speculates that technology could enable commanders to "move from a situation in which decision making takes place under 'uncertainty' or in the presence of incomplete and erroneously information, to a situation in which decisions are made with near 'perfect' information."⁸⁹

The future concepts described by Owens and others are built on technology-intensive processes at the operational level of war in two key areas. First, they increasingly rely on analysis and synthetic representations of the battlespace to support decision makers. Second, they rely on technology to compress friendly decision cycle times in order to operate inside the adversary's decision cycle—his OODA loop.⁹⁰ Could similar technology-intensive approaches achieve the efficiencies and reliable discriminate outcomes at the strategic level of war promised by strategic precision engagement? There is evidence to suggest otherwise: that a technology-intensive "solution" to strategic precision engagement will in fact increase the potential for strategic failure.

The “Side Effects” of Technology Intensive Approaches

In his book, *Why Things Bite Back*, Edward Tenner describes how high-tech approaches to complex problems frequently produce what he terms “revenge effects.” He cites numerous examples from the fields of industry, medicine, biology and social sciences where technology fixes increased demand in ways that offset expected efficiencies, introduced new complications to the original problem or sometimes altered the nature of problem itself, often in unexpected ways.

Consider the case of precision munitions. In improving the reliability and efficiency of force application, the demonstrated capabilities of such technologies have also amplified the significance of individual casualties and instances of collateral damage. The result has been greater demand to use precision capabilities—a consequence of what Foster and Welch describe as the imperative of precision.⁹¹ Moreover, Author William Arkin notes that today “every weapon counts. Targets have to be meticulously chosen and the choreography of a conflict becomes ever more essential.”⁹² When an improved capability increases the demands placed on that capability it is an example of what Tenner calls a redoubling or repeating effect of technology.⁹³

The choreography of conflict increases the need for technological fixes to speed decision support through analysis and synthetic representations of the strategic situation. Confidence in the tools leads to even greater dependence.⁹⁴ However, Tenner found evidence that such dependence makes the decision makers susceptible to a phenomenon that psychologists call the “illusion of control.”

(W)e can easily convince ourselves, given the proper setting, that we’re making things happen when in reality they are chance events. Both the beauty and the risk of computerized analysis is the concreteness it can give our plans—even when our underlying data are doubtful and our models untested or even wrong. We have seen the theatrical power of computers; in the illusion of control, we turned on ourselves to reassure ourselves that the powers we possess are indeed real.⁹⁵

The danger, according to Tenner, is that decision makers will develop “inappropriate confidence” in the technological tools that guide their decisions.

A decade ago in their book, *War Ends and Means*, Paul Seabury and Angelo Codevilla argued a similar point in describing how the Cold War emphasis on force ratios and the mechanics of ballistic missile targeting led to unrealistic faith in the ability of systems analysis to produce meaningful strategic assessments.⁹⁶ They noted that such systems analysis created an aura of objectivity that enabled senior decision makers “to exercise power while keeping the option of claiming they are not responsible for eventual failures because they acted ‘by the numbers.’”⁹⁷ Tenner finds a tendency that “the better and safer technology becomes, the more we presume human error when something goes seriously wrong. If it is not the error of the captain or the crew, it is one of the engineers or designers of equipment, or of executives and their maintenance policies.”⁹⁸ While success is a result of superior technology and training, failures must be a result of mistakes by the policy makers, the intelligence analysts, the controllers or the weapon system operators rather than the underlying technological construct itself.

Tenner also found evidence that technology-intensive solutions incur a “burden of vigilance” that ultimately offsets the expected efficiencies that justified the course of action the first place.⁹⁹ He describes how banks sought to realize savings by replacing accountants with computing technologies only to find that the increased computer power led to far greater demand than expected, and the predicted savings were eaten up by the need to ensure the software and hardware continued to perform.¹⁰⁰

Strategic precision engagement demands increased vigilance in two ways. First, especially given insights from the previous chapter regarding nonlinear and complex adaptive systems, strategic precision engagement will demand increased “quality control” over the technologies and processes of intelligence collection, analysis, planning, and execution to avoid perturbations in the form of foul-ups, glitches, and other mistakes. A second burden of vigilance is the increased need to “protect” the technological infrastructure on which strategic precision engagement depends from enemy spoofing or and even direct attack. There is plenty of evidence that at least one potential strategic competitor, China, is already focusing on ways to exploit such dependencies.¹⁰¹

Tenner’s findings support arguments by Barry Watts that friction will persist in future war despite important contributions of technology.¹⁰²

Moreover, Tenner's research suggests that technological fixes to strategic precision engagement are likely to *introduce* new sources of friction that will be difficult to assess or even envision ahead of time. As the next section will explain, the resultant combination of redoubling, potential for inappropriate confidence, and demands of vigilance are especially problematic revenge effects for a concept that depends on tight control and feedback to synchronize lethal force with desired discriminate effects.

Process Coupling And System Accidents

In the 1980s organizational theorist Charles Perrow studied organizations responsible for managing complex and technology-intensive processes and concluded that some systems were inherently prone to what he called a "system accident." His book, *Normal Accidents*, provides detailed case studies from the nuclear power and petrochemical industries.

Perrow found it useful to classify processes according to the complexity of system interactions and the degree of coupling inherent in those interactions. He described system interactions as either linear or complex. "Linear interactions are those in expected and familiar production or maintenance sequence, and those that are quite visible even if unplanned....Complex interactions are those of unfamiliar sequences, or unplanned and unexpected sequences, and either not visible or not immediately comprehensible."¹⁰³

Perrow used the term coupling to describe the degree of slack present within the system. He described loosely coupled systems as decentralized, and having flexible control mechanisms and many pathways to a desired outcome.¹⁰⁴ Such systems can incorporate shocks, failures, and pressures for change without destabilization, they can shift into a standby mode without seriously disrupting the ultimate outcomes, and they allow for "expedient, spur-of-the-moment buffers and redundancies...even though they were not planned ahead of time."¹⁰⁵ In contrast, tightly coupled systems are highly centralized, built around inflexible procedures and extremely sensitive to perturbations.¹⁰⁶ Tightly coupled systems are not amenable to make-shift responses and therefore require extensive up-front planning to think of and build in buffers, redundancies and alternative courses of action to deal with contingencies.¹⁰⁷

Perrow concluded that processes characterized by tightly coupled, complex interactions were prone to system accidents, which he defined as “a failure in a subsystem, or the system as a whole, that damages more than one unit and in doing so disrupts the ongoing or future output of the system.”¹⁰⁸ He notes that systems experience small failures all the time. Even where complex interactions are involved, small failures can be managed through built-in safety mechanisms as well as experienced and quick thinking operators.¹⁰⁹ However, Perrow illustrates how “two or more failures, none of them devastating in themselves in isolation, [can] come together in unexpected ways and defeat the safety devices. If the system is also tightly coupled, these failures can cascade faster than any safety device or operator can cope with them, or they can even be incomprehensible to those responsible for doing the coping.”¹¹⁰

Perrow points out that complex system coupling is particularly worrisome when the underlying technologies have a high catastrophic potential, which he defines as the degree to which a system accident could “cause damage to a great many humans.”¹¹¹ His most compelling case studies come from the nuclear power and petrochemical industries where the catastrophic potential is high.

Strategic Precision Engagement and Complex System Coupling

An approach that seeks technological fixes to the assumptions behind strategic precision engagement could easily contribute to the very factors that tend to produce the system accidents described by Perrow. First, technology can certainly improve direct measurements of actions and effects, but the overwhelming volume of raw data increases dependence on technology to prioritize and fuse that data: “there is only so much that any human can absorb, digest, and act upon in a given period of time.”¹¹² More importantly, some information will remain hidden or inaccessible from *a priori* direct measurement because of the contingent nature of the underlying interactions of the black box.¹¹³ Add to this Tenner’s evidence that organizations tend to develop inappropriate confidence in sophisticated technology “solutions,” and it seems apparent that technology does not resolve, and in fact may exacerbate, an organization’s inability to observe or even comprehend all the interactions involved in the system—the hallmarks of complexity.

Second, the demonstrated ability of seemingly minor interactions to generate strategic effects will create powerful incentives to tightly synchronize operations at all levels of command. Unfortunately, tighter synchronization is equivalent to increased process coupling. In such circumstances, Van Crevald explains how “a failure at any point may put the entire chain in jeopardy—when, for instance, a decision is based on an out-of-date piece of information.”¹¹⁴ While multiple errors can sometimes “cancel each other out” other errors will reinforce one another in a negative synergy.¹¹⁵ In 1994 a combination of multiple “small” failures of command and control ultimately led to the accidental shoot down of two friendly Blackhawk helicopters. Similarly, the bombing of the Chinese Embassy in Belgrade and bombing of refugees outside Dakovica, Kosovo during OPERATION ALLIED FORCE were not the result of one grossly negligent act, but of a combination of individual failures that unfortunately came together to produce a “system accident.”

Third, technological fixes introduce more insidious and vexing sources of complexity and coupling. Software design expert Watts Humphrey warns, “most engineers seem to think that testing will find their defects.... [I]t is an unfortunate fact that programs will run even when they have defects. In fact, they can have a lot of defects and still pass a lot of tests. To find even a large percentage of the defects in a program, we would have to test almost all the logical paths and conditions. And to find all of the defects in even small programs, we would have to run an exhaustive test.”¹¹⁶ This is especially troubling because “the seriousness of a defect does not relate to the seriousness of the mistake that caused it.”¹¹⁷ According to Humphrey, some of industry’s most costly software defects have been the result of “trivial typing mistakes.”¹¹⁸ Moreover, having a crack team of software programmers and analysts on hand does not solve the problem. Tenner notes that the sheer complexity of the underlying software architecture means “every feature that is added and every bug that is fixed adds the possibility of some new and unexpected interaction between parts of the program. A small change to solve a minor problem may create a larger one.”¹¹⁹

Based on Perrow’s research and the above observations, it appears that technological “fixes” tend to increase system complexity and coupling and thereby increase the overall potential for a system accident. The most dangerous revenge effect of a high-tech fix to strategic precision engagement is the false sense of strategic control it might create. What about the catastrophic potential of a strategic precision engagement

accident? An accident involving lethal force clearly risks “damage to humans,” both intentional and unintentional. Yet strategic precision engagement accidents have other repercussions that extend well beyond direct battlefield casualties. A system accident could generate effects that alter the strategic environment in ways that require significantly more time, resources, lives or political capital to achieve an acceptable end state or perhaps even force the abandonment of the original aims. This is not merely a problem for the politicians, and therefore outside the pure military aspects of strategic precision engagement. If, given prior knowledge of those strategic effects, a political leader might choose a different course of action, should not those effects be included in an assessment of catastrophic potential? In this sense, the catastrophic potential of strategic precision engagement lies in the ability for a system accident to disproportionately complicate the strategic environment relative to the original expectations. All of these are the consequences of using a technology-intensive and thus a complex and tightly coupled approach to achieving strategic leverage through discriminate effects.

As a result, some experts paint an optimistic picture of a technology-enhanced battlespace of the future; there is substantial evidence that the technology fixes could inject inappropriate confidence into our understanding of the cause and effect relationships of the black box. This is not an argument to spurn technology since, as Gen Charles Boyd notes, “Technology works and saves lives, on both sides.”¹²⁰ However, the technology fixes needed to “steer” interactions towards discriminate outcomes will tend to increase system complexity and coupling and thereby increase the potential for a system accident.

VI. Conclusions

“Failure never comes easily, but it comes especially hard when success is anticipated at little cost.”¹²¹

–George C. Herring

Over a thousand years ago, the Greek philosopher Zeno used formal logic to deconstruct physical distance in a way that “proved” the impossibility of motion.¹²² The example of Zeno’s paradox cautions against claiming that the deconstruction presented in this paper has “proven” the impossibility of strategic precision engagement, despite evidence that the concept suffers from important weaknesses. However, the insights revealed through this deconstruction do argue for greater clarity and more realism in how aerospace doctrine connects tactical action to strategic effect. Specifically, doctrine needs to differentiate between technical exactness and strategic correctness; recognize that foreclosing adversary option sets is more reliable than compelling specific, predetermined behaviors; and emphasize the central role of adaptation in effects-based concepts.

Recapping the Main Issues

This paper argues that delivering desired discriminate effects at the strategic level of war rests on three necessary assumptions: the ability to define desired discriminate effects at the strategic level of war, the ability to trace the discriminate effects back to a triggering action, and the ability to ensure the *actual* effects generated by that action are only the discriminate ones being sought. A close examination of these assumptions reveals some important conceptual weaknesses that are further amplified when the problem is examined from the perspective of nonlinear and complex adaptive systems.

In nonlinear and complex systems, overall behavior can be quite different than what might be predicted from a detailed examination of system components: strategic effects are not simply the sum of tactical and operational effects. In such systems, small perturbations can generate disproportionate effects: each interaction is potentially critical. But the

contingent nature of interactions within complex human systems means that the full spectrum of strategic effects may be unknowable. Many external interactions will fall outside the military's ability to control, further complicating the prediction of strategic effects. Finally, each engagement with an adversary provides stimulus for evolution, sometimes in discontinuous ways, so that identical actions do not always produce identical effects. The intrinsic nature of perturbations and unexpected discontinuities are problematic for a concept that seeks to achieve discriminate strategic effects with reliability.

The paper also found evidence that technological "fixes" are not likely to eliminate the weaknesses inherent in the assumptions of strategic precision engagement, despite stunning advances in technological capabilities. Attempts to exercise tight control through processes that quickly recognize and respond to emergent strategic effects also increase system coupling and the potential for system accidents. Moreover, the technology that enables individual actions to affect strategic outcomes directly also means that the impact of a system accident can be severe if not catastrophic relative to the intended strategy. This conclusion undermines the assumption that the *actual* effects generated by that action are only the discriminate ones being sought. Moreover, the paper presents evidence to doubt whether strategic precision engagement could ever achieve the strategic efficiencies implied. In seeking to solve the strategic problem, it is quite possible that the technological "fixes" would create inefficiencies or demands for resources in other areas of the system.

In the face of these weaknesses, precision engagement seems ill suited as a concept for dealing with the strategic level of war. As a minimum, it can lead to inappropriate confidence in estimating the amount of time and resources that will be required to achieve a particular outcome. Even if one could somehow mitigate the potential for system accidents to result in catastrophe, the evidence suggests strategic precision engagement will not be able to achieve the reliability, effectiveness or even the efficiencies it promises. Such insights argue the need for doctrine to take a more realistic and more modest approach when relating tactical cause to strategic effect.

Realism and Technological Modesty

In studying the Allied Combined Bomber Offensive of World War II, military historian Williamson Murray concluded that the “short-fall between expectations and realities [was] so noticeable [because] airmen regarded their weapons and their doctrine as a guarantee for victory—one that they could achieve without the terrible attrition that had so marked World War I. The greatest surprise of the war turned out to be the fact that the same conditions and rules governed air war as governed the more traditional forms of combat.”¹²³ Modern technology makes aerospace power particularly susceptible to the sort of overconfidence that Murray describes. In *Airpower and the Cult of the Offensive*, Major John Carter argues that, “The continuing acquisition of stealth platforms and precision munitions will lead to an arsenal of weapons increasingly well-suited for offensive action. When combined with the belief that any enemy is a fragile system, susceptible to manipulation by the delivery of a small number of well-placed munitions, the trap of offensive ideology is set.”¹²⁴ According to Carter, such a trap risks operational and strategic failure.¹²⁵

Strategic precision engagement is a potential trap for aerospace power because it assumes an unrealistic congruency between technology and war. Martin Van Creveld reminds us “technology and war operate on a logic which is not only different but actually opposed, the conceptual framework that is useful, even vital, for dealing with the one should not be allowed to interfere with the other.”¹²⁶ Watts sees an inherent contradiction created by casting war as fundamentally a social phenomenon on the one hand, while attempting to reduce it to technological means on the other. Watt’s arguments force us to conclude that strategic precision engagement’s dependence on a reduction in the absolute level of friction makes it “a false issue that diverts attention from the real business of war.”¹²⁷ In short, one way for doctrine to be more realistic is to incorporate greater technological modesty—perhaps even technological humility—when relating tactical cause to strategic effect.

Exactness Versus Correctness: The Need for Clarity

The first dose of technological modesty requires doctrine to be clear that strategic correctness is an entirely different issue than engineering exactness when it comes to aerospace precision. By failing to separate the

two concepts, current doctrine superimposes the logic of technological efficiency and one-to-one relationships between cause and effect onto what Van Crevald calls the “paradoxical” nature of war. This approach clearly conflicts with insights from the study of nonlinearity and complex systems and the counter-intuitive result that more exact actions on the input side of a strategic black box do not necessarily lead to more correct effects on the output side. Flawless execution does not necessarily produce desired, discriminate effects. And if flawless execution cannot guarantee such effects, flawed execution presents far more serious challenges, since “perturbations” can generate disproportionate effects. By blending correctness and exactness, doctrine reinforces the potential for unrealistic expectations and strategic blind spots.

Doctrine should not attempt to apply the logic of precision beyond its ability to generate and apply “brute destructive force” with efficiency and reliability.¹²⁸ The exactness of precision provides commanders with valuable options relative to time-honored principles of war, such as mass and economy of force. The exactness of precision offers what airpower historian Richard Hallion calls “clear advantages in reducing risk to attacking forces.”¹²⁹ However, the exactness of precision does not obviate critical uncertainties in the transformation of tactical action into strategic effect.

Foreclosing Adversary Options

An alternative and more realistic paradigm of precision force emerges when one de-emphasizes the pursuit of discriminate strategic effects. This alternative approach emphasizes precision as a means to foreclose adversary options rather than compel specific, predetermined behaviors. For example, blowing up a bridge with a precision weapon forecloses the adversary option, at least temporarily, of relying on the continued functioning of that bridge to exercise his strategic options. Using precision to deny options has the effect of narrowing enemy flexibility to adapt—to constrain what Watts calls “option sets in possibility space.” This suggests a more appropriate paradigm for employing precision force: one which focuses less on the achievement of discriminate outcomes and focuses more on the discriminate attrition of options.

Of course, the only way to ensure that a *specific* effect will occur—that a *specific* choice will be made—is to eliminate *all* the other

alternatives. This alternative paradigm promises far less than what current doctrine implies with strategic precision engagement. It is, however, far more realistic. Speaking at the Unified Aerospace Power Conference, General Clark described how “we knew exactly what it took to take out Serb petroleum production. We hit it, and when the cloud covers left we saw fuel barrels being unloaded from barges on the Danube. Obviously the Serbs could get fuel from somewhere else.”¹³⁰ Clearly, there are immense challenges in determining the full range of strategic alternatives open to the adversary and we must be prepared for “surprise.”

Effects-Based Adaptation

The switch in paradigms does not require the abandonment of effects-based approaches in the pursuit of greater realism and clarity. Effects-based approaches can provide important sources of strategic coherence to military operations, similar to how centers of gravity allow us to “focus our own efforts.”¹³¹ Effects-based approaches also provide a language of discourse during the targeting process, and enable decision makers conceptualize and manage operational priorities.

Yet doctrine must be clear that strategic *coherence* is not equivalent to strategic *knowledge*. Even with partial insight into the strategic black box, important underlying system interactions and linkages will remain latent and inherently unknowable until the system is stimulated. This is an important point for operational concepts that seek to influence the adversary’s *hub* of power and movement. Even though data management systems like the Joint Targeting Toolbox have the potential to increase transparency in the targeting process, they do not provide “knowledge” any more than they substitute for the insight, judgment, subtlety, balance and finesse captured in the Clausewitzian concepts of *coup d’oeil* and *commander genius*.

As a result, effects-based approaches should place less emphasis on absolute prediction and more emphasis on flexibility, both operational and intellectual. General John Jumper’s counsel “not to start anything where the only plan consists of one phase” should not be interpreted as a call to develop highly detailed multi-phase operations plans but as a call for intellectual and operational flexibility.¹³² Operational flexibility is needed since effects are not “givens” to be achieved through a predetermined sequence of target sets, and “more” does not equate to “more likely.”

Intellectual flexibility is needed in order to avoid a dogged, single-minded pursuit of an effect that is no longer important or even obtainable in an evolutionary system of strategic interactions.

In both cases, flexibility requires an open and continuous sharing of information and challenging of underlying strategic assumptions across all dimensions (economic, political, military, social). Flexibility requires multi-disciplinary collaboration right down to the targeting level to reduce the possibility of targeting becoming a technical or social “engineering” problem. One military expert has suggested the need to put more emphasis on socio-cultural considerations as part of the targeting process:

The targeting you have to do yourself and it involves intelligence. But as General Jumper found out, and a crucial point, the Serbian population forced Milosovic to call the war off when the life of the Serbian population was made very uncomfortable. Other populations will not have that reaction. Other populations are simply used to it, are passive, they are used to being maltreated and you can then persecute and make their lives so dramatic. The question is what is the difference between the Serbs and Iraq. You cannot photograph that difference. It is a question of culture and General Eaker would have said that is the right thing. The U.S. Air Force needs a department of culture.¹³³

Flexibility casts technologies in the role of stimulus and response, seeking to expose the adversary’s secrets in order to apply precision force in ways that narrow his options. Flexibility requires error tolerance and avoidance of over-control. It explicitly prepares for operations beyond a priori estimates.

In the end, the language of strategic precision engagement needs a booster shot of Clausewitzian friction. Williamson Murray believes that “only the marines appear to be solidly resisting the allure of technology as the answer to all the problems of war in the next century.” Murray cites the “pervasive Clausewitzian flavor” of Marine Corps doctrine and their “sense of history both as a learning tool and as a warning to those who would put too much reliance on technology.”¹³⁴ Marine Corps doctrine continuously emphasizes the centrality of dynamic, human interactions in war.¹³⁵ It states that, “The occurrences of war will not unfold like clockwork. We cannot hope to impose precise, positive control over

events.”¹³⁶ Instead, commanders should seek to “impose a general framework of order on the disorder, to influence the general flow of action,” based on their best judgment of probabilities and enemy intent, recognizing that “it is precisely those [actions] that seem improbable that often have the greatest impact on the outcome of war.”¹³⁷ At the strategic level of war, boldness and decisiveness must “be tempered with an appropriate sense of balance and perspective.”¹³⁸

Hopefully, a booster shot of Clausewitzian friction would keep strategic precision engagement from obscuring a fundamental truth described by Paul Seabury and Angelo Codevilla in their book, *War: Ends and Means*, “Anyone entering the fog [of war] is best advised to look at all things he can see and control from the perspective of the only reliable compass: the idea of victory—the attainment of the goal for which he is fighting.”¹³⁹

Conclusion

Paul Seabury and Angelo Codevilla remind us “the fog that surrounds the outcomes of war has always tempted people to spin theories about what lies on the other side. Yet reality is always a surprise.”¹⁴⁰ The evidence suggests that strategic precision engagement spins a theory of warfare that is unrealistic and even dangerously misleading. Strategic precision engagement requires the careful untangling of Gordian knot characterized by complex connections between tactical input, mechanisms and dynamics within the enemy and our own system, and expected effects or outcomes. Discriminate strategic effects are not an automatic consequence of aerospace precision. Such shortcomings suggest that strategic precision engagement involves too much wishful thinking to be a reliable, guiding promise for aerospace power.

Having said that, the author doubts whether purely analytical arguments will ever provide a clear demarcation between what we actually “know” to be true versus what we would “like” to be true about the connection between tactical action and strategic effect. In any case, aerospace doctrine is not science—it tends to be empirical and inductive rather than analytical and deductive and it remains in constant evolution—a “work in progress.”¹⁴¹ In that vein, it is hoped that the arguments presented in this paper will motivate further debate over the relationship between technical exactness and strategic correctness, and thereby

contribute positively to the evolution of aerospace doctrine. Moreover, such debate will be critical in exposing strategic blind spots and potential revenge effects of precision technologies. Unfortunately, assured efficiency and effectiveness in achieving discriminate strategic outcomes is likely to remain an alluring idea, perpetually abetted by increasingly sophisticated precision and computing technologies. In such an environment, technological humility will be a difficult pill to swallow.

¹² Hawley, General Richard E., et al., "Global Reconnaissance-Strike," *Armed Forces Journal International*, June 2000, p. 52. General Hawley praises the role of long-range strike assets in Operation Allied Force. Global-strike aircraft operating from the U.S., U.K., and off of aircraft carriers delivered two-thirds of the total allied firepower while comprising only one-fifth of the strike assets available. Further, on many nights with bad weather, B-2As were NATO's sole strike option, preventing lulls in allied activity that could have been exploited by our opposition. In Hawley's words, it was "FEDEX-like reliability straight from America's heartland."

⁵⁴ *Air Warfare*, 22 January 2000, p. 51

⁵⁵ *Ibid.*, 3. While doctrine uses the term mechanism to refer to the connection between action and effect, it does not provide a formal definition of mechanism. AFDD 2-1's glossary incorporates the term mechanism into the definitions of direct and indirect effects. It defines direct effect as the "result of actions with no intervening effect or mechanism between act and outcome. Direct effects are usually immediate and easily recognizable." An indirect effect is the "result created through an intermediate effect or mechanism to produce the final outcome, which may be physical or psychological in nature. Indirect effects tend to be delayed and may be difficult to recognize." AFDD 2-1, 106, 107. Even the most recent draft of AFDD 2-1.2, *Strategic Attack*, fails to provide a definition even though it uses the term repeatedly.

¹²² Zeno noted that for an object to travel a specified distance, it must first travel half that distance, then half the remaining distance (one-fourth of the original distance), then half of that remaining distance (one-eighth the original distance) and so on, *ad infinitum*. Using this logic, he argued that moving from any point A to any point B requires an infinite sum of nonzero time intervals—i.e., an infinite amount of time—and thus concluded motion must be impossible. Clearly this result is absurd. The invention of calculus, which came later, proved that some infinite sums converge toward finite numbers.

54...Precision Engagement at the Strategic Level of

Center for Strategy and Technology

The Center for Strategy and Technology was established at the Air War College in 1996. Its purpose is to engage in long-term strategic thinking about technology and its implications for U.S. national security.

The Center focuses on education, research, and publications that support the integration of technology into national strategy and policy. Its charter is to support faculty and student research, publish research through books, articles, and occasional papers, fund a regular program for guest speakers, host conferences and symposia on these issues, and engage in collaborative research with U.S. and international academic institutions. As an outside funded activity, the Center enjoys the support of institutions in the strategic, scientific, and technological worlds.

An essential part of this program is to establish relationships with organizations in the Air Force as well as other Department of Defense agencies, and identify potential topics for research projects. Research conducted under the auspices of the Center is published as Occasional papers and disseminated to senior military and political officials, think tanks, educational institutions, and other interested parties. Through these publications, the Center hopes to promote the integration of technology and strategy in support of U.S. national security objectives.

Titles in the Occasional Papers Series

1

Reachback Operations for Air Campaign Planning and Execution

Scott M. Britten, September 1997

2

Lasers in Space: Technological Options for Enhancing U.S. Military Capabilities

Mark E. Rogers, November 1997

3

Non-Lethal Technologies: Implications for Military Strategy

Joseph Siniscalchi, March 1998

4

Perils of Reasoning by Historical Analogy: Munich, Vietnam, and the American Use of Force Since 1945

Jeffrey Record, March 1998

5

Lasers and Missile Defense: New Concepts for Space-Based and Ground-Based Laser Weapons

William H. Possel, July 1998

6

Weaponization of Space: Understanding Strategic and Technological Inevitables

Thomas D. Bell, January 1999

7

Legal Constraints on Information Warfare

Mark Russell Shulmann, March 1999

8

Serbia and Vietnam: A Preliminary Comparison of U.S. Decisions to Use Force

Jeffrey Record, May 1999

9

Airborne and Space-Based Lasers: An Analysis of Technological and Operational Compatibility

Kenneth W. Barker, June 1999

10

Directed Energy and Fleet Defense: Implications for Naval Warfare

William J. McCarthy, February 2000

11

High Power Microwaves: Strategic and Operational Implications for Warfare

Eileen M. Walling, March 2000

12

Reusable Launch Vehicles and Space Operations

John E. Ward, Jr., March 2000

13

Cruise Missiles and Modern War: Strategic and Technological Implications

David J. Nicholls, March 2000

14

Deeply Buried Facilities: Implications for Military Operations

Eric M. Sepp, March 2000

15

Technology and Command: Implications for Military Operations in the Twenty-First Century

William B. McClure, July 2000

16

Unmanned Aerial Vehicles: Implications for Military Operations

David Glade, July 2000

17

Computer Networks and Information Warfare: Implications for Military Operations

David J. Gruber, July 2000

18

Failed States and Casualty Phobia: Implications for Force Structure and Technology Choices

Jeffrey Record, December 2000

19

War as We Knew It: The Real Revolution in Military Affairs/Understanding Paralysis in Military Operations

Jan S. Bremer, December 2000

20

Using Lasers in Space: Laser Orbital Debris Removal and Asteroid Deflection

Jonathan W. Campbell, December 2000

21

Weapons for Strategic Effect: How Important is Technology?

Collin S. Gray, January 2001

22

U.S. Army Apache Helicopters and U.S. Air Force Expeditionary Forces: Implications for Future Military Operations

Brad Mason, June 2001

23

The End of Secrecy? Military Competitiveness in the Age of Transparency

Beth M. Kaspar, August 2001

24

Prompt Global Strike Through Space: What Military Value?

Larry G. Sills, August 2001
